Codebook

This document describes the table produced by run_analysis.R.

This table is formed by merging the X training and test tables and then each row to the id from the y training and test table. The resulting table has 562 colums, corresponding to the id and the 561 features from features.txt.

The mean for each feature for each id is then computed and the output table has a row corresponding to each id and 561 columns corresponding to the features. Each entry is the average for that feature and id.
